

CLA Website Architecture OS v1

Section 1 — Website Architecture

STATUS: APPROVED

Purpose

This document defines the technical architecture of the CLA website.

Its purpose is to ensure the project remains organized, scalable, maintainable, and easy to develop for many years.

Folder Structure

The website uses a feature-based architecture.

Content is organized by responsibility rather than file type whenever practical.

The structure should remain clean, predictable, and easy to navigate.

Component Organization

A shared /components library is preferred.

Page-specific components may remain inside their page folders when that improves maintainability.

The primary goal is simplicity and long-term maintainability rather than rigid rules.

Content Organization

Content should remain separate from presentation whenever practical.

HTML, styling, scripting, and content should have clearly defined responsibilities.

This allows easier translation, maintenance, and future expansion.

Naming Convention

CamelCase is the official naming convention.

Examples:

- * heroSection.js
- * prayerRequest.html
- * eventCard.css

Naming should remain descriptive and consistent.

Images

The current image organization is considered the standard.

Future changes should improve clarity rather than reorganize for the sake of reorganization.

CSS Architecture

The project uses:

- * One global stylesheet
- * Component-specific stylesheets

Each component manages its own styling while shared styles remain centralized.

JavaScript Architecture

JavaScript is modular.

Each feature or component owns its own JavaScript whenever practical.

Large monolithic JavaScript files should be avoided.

Configuration

Reusable configuration should remain centralized.

Examples include:

- * Colors
- * Breakpoints
- * Constants
- * URLs
- * Translation configuration
- * Global settings

Hardcoded values should be minimized whenever practical.

Guiding Principle

The architecture should make development faster—not more complicated.
